Statistical analysis of the data was performed using the SPSS statistical software package (SPSS Inc., Chicago, IL). Descriptive statistics were used to describe the characteristics of the study population. Univariate analysis was used to determine the association between the independent variables and the outcome variables. The independent variables included age, sex, marital status, education level, occupation, income, and smoking status. The outcome variables included the presence of hypertension, diabetes, and cardiovascular disease. The results were presented as frequencies and percentages for categorical variables and as means and standard deviations for continuous variables. The significance level was set at 0.05.
